

# Wave functions beyond Slater–Jastrow

Pablo López Ríos Neil D. Drummond

University of Cambridge Lancaster

27th July, 2016

# The Slater determinant

- Basic antisymmetric wave function: a Slater determinant

$$\Psi_S(\mathbf{R}) = \begin{vmatrix} \phi_1(\mathbf{r}_1) & \phi_1(\mathbf{r}_2) & \dots & \phi_1(\mathbf{r}_N) \\ \phi_2(\mathbf{r}_1) & \phi_2(\mathbf{r}_2) & \dots & \phi_2(\mathbf{r}_N) \\ \vdots & \vdots & \ddots & \vdots \\ \phi_N(\mathbf{r}_1) & \phi_N(\mathbf{r}_2) & \dots & \phi_N(\mathbf{r}_N) \end{vmatrix}$$

- If  $\hat{H}$  is independent of spin, can factor spatial wave function into up- and down-spin parts:

$$\begin{vmatrix} \phi_1(\mathbf{r}_1^\uparrow) & \dots & \phi_1(\mathbf{r}_{N_\uparrow}^\uparrow) \\ \vdots & \ddots & \vdots \\ \phi_{N_\uparrow}(\mathbf{r}_1^\uparrow) & \dots & \phi_{N_\uparrow}(\mathbf{r}_{N_\uparrow}^\uparrow) \end{vmatrix} \begin{vmatrix} \phi_1(\mathbf{r}_1^\downarrow) & \dots & \phi_1(\mathbf{r}_{N_\downarrow}^\downarrow) \\ \vdots & \ddots & \vdots \\ \phi_{N_\downarrow}(\mathbf{r}_1^\downarrow) & \dots & \phi_{N_\downarrow}(\mathbf{r}_{N_\downarrow}^\downarrow) \end{vmatrix}$$

- Orbitals  $\{\phi\}$  can be obtained from HF, DFT, etc.

# The Slater–Jastrow wave function

- Electronic correlation introduced using a multiplicative Jastrow factor,

$$\Psi_{SJ}(R) = \exp[J(R)] \Psi_S(R)$$

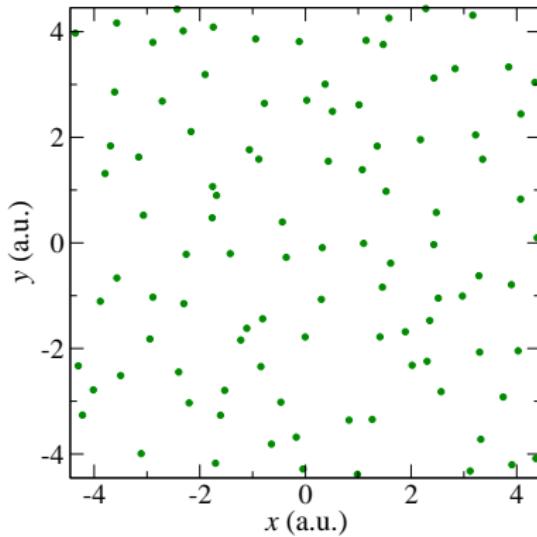

- Advantages of using a Jastrow factor:
  - Compact form
  - Fulfils Kato cusp conditions → much improved statistics
  - Good description of electronic correlation → ability to retrieve 70–85% of the correlation energy in VMC

# Need for better wave functions

Why do we need better wave functions?

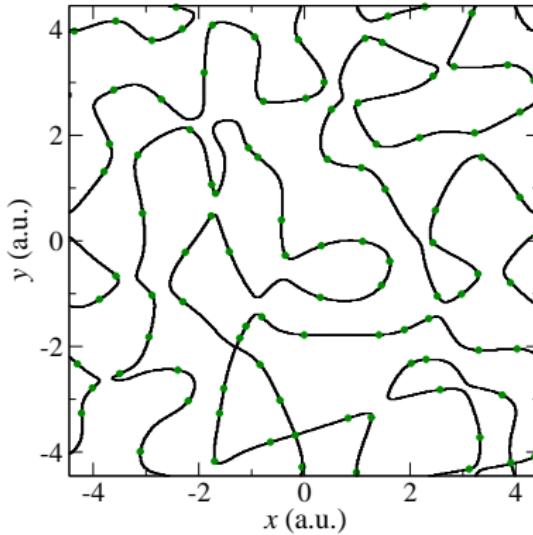

- DMC energies depend on the nodes of  $\Psi$ , but Jastrow factors do not modify the nodes of  $\Psi_S$
- We want **chemical accuracy** ( $\equiv 1.5$  mHa away from ground state energy at most)
- Expectation values other than the energy are **sensitive** to the quality of the wave function
- Improving  $\Psi$  and its nodes involves interesting Physics/Maths

# How hard can nodes be?

An innocent 2D HEG, a “simple” system

# How hard can nodes be?

An innocent 2D HEG, a “simple” system

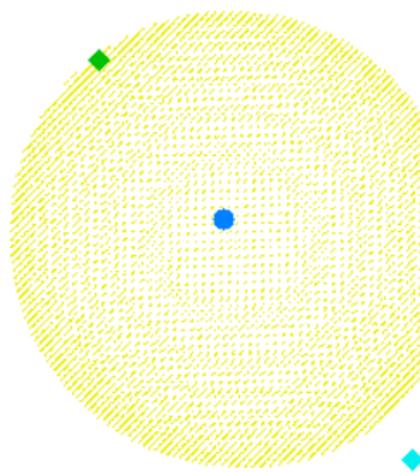

# How hard can nodes be?

The nodes of  $\Psi_{\text{SJ}}$ :

- Have **no** connection with the nodes of the orbitals
- Are **rarely sampled** → are **hard to optimise** within standard schemes → but are **the source of error** anyway
- Tend to divide config space into too many regions (nodal pockets) → tend to have the **wrong topology** (should satisfy a **tiling property**)
- Are not too far away from the true answer

# How hard can nodes be?

HF nodes vs. exact nodes

Beryllium atom

# Possible wave functions

- Optimise the **orbitals** in the determinants
- Borrow techniques from Quantum Chemistry  
→ **multi-determinant** expansions
- Make the orbitals depend on the inter-electronic distances, by
  - Using **pairing**/**(multi-)geminal**/**(multi-)Pfaffian** wave functions
  - Using coordinate transformations → **backflow**

# Orbital parametrisation

- In atomic systems, modify the radial function,

$$\phi_{nlm}(\mathbf{r}) = [\rho_{nl}^{\text{HF}}(r) + \Delta\rho_{nl}(r)] r^l Y_{lm}(\theta, \phi)$$

with

$$\Delta\rho_{nl}(r) = \left( \sum_{j=0}^{N_p} c_{jnl} r^j \right) \exp\left(\frac{-A_{nl}r^2}{1+B_{nl}r}\right)$$

N. D. Drummond *et al.*, J. Chem. Phys. **124**, 224104 (2006)

- In small molecules one can expand the orbitals in a Slater basis  
C. Filippi and C. J. Umrigar, J. Chem. Phys. **105**, 213 (1996)
- If using Gaussians, can optimise the expansion coeffs and the exponents

# How well does orbital optimisation work?

- Variable degree of success in different studies
- In general the results are not all that impressive, e.g.,
  - VMC for AE Ne and  $\text{Ne}^+$  → it retrieves  $\sim 12\%$  of the difference between VMC with HF orbitals and the exact answer
  - DMC for AE Ne and  $\text{Ne}^+$  → it retrieves  $\sim 3\%$  of the difference between DMC with HF orbitals and the exact answer → **little nodal improvement**
  - VMC and DMC for PP Ne and  $\text{Ne}^+$  → it retrieves  $\sim 2\%$  of difference with exact answer

# Multi-determinant expansions

- The eigenstates  $\psi_n(\mathbf{r})$  of a single-particle Hamiltonian  $\equiv$  **basis** for functions of  $\mathbf{r}$   $\rightarrow$  the determinants constructed from combinations of  $N$  orbitals for  $N$  particles  $\equiv$  **basis for antisymmetric functions** of  $\mathbf{R}$   $\rightarrow$  the exact wave function is

$$\Phi_0(\mathbf{R}) = \sum_{k=0}^{\infty} c_k D_k(\mathbf{R})$$

(similarly with spin-splitting)

- Notice that  $c_k = \delta_{0k}$  corresponds to the **Hartree-Fock** wave function

# Applicability

- Small atoms → great results
- Small molecules → great results too
- Medium-size systems hard
- Large/crystalline systems impossible

Ideally, we would like to depend less strongly on system size

# Geminal wave function

Functional form:

$$\Psi_S^{\text{gem}}(\mathbf{R}) = \det \left| \Gamma \left( \mathbf{r}_i^\uparrow, \mathbf{r}_j^\downarrow \right) \right|$$

where

$$\Gamma \left( \mathbf{r}^\uparrow, \mathbf{r}^\downarrow \right) = \sum_{kl} \gamma_{kl} \phi_k^\uparrow(\mathbf{r}^\uparrow) \phi_l^\downarrow(\mathbf{r}^\downarrow)$$

Subject of current research.

# The Slater–Jastrow-backflow wave function

The backflow transformation is applied on SJ wave functions giving

$$\Psi_{\text{BF}}(\mathbf{R}) = \exp[J(\mathbf{R})] \Psi_S[\mathbf{X}(\mathbf{R})]$$

where  $\mathbf{X}$  is a vector of *quasi-particle* coordinates,

$$\mathbf{x}_i(\mathbf{R}) = \mathbf{r}_i + \xi_i(\mathbf{R})$$

Explicitly,  $\Psi_S(\mathbf{R})$  is replaced by

$$\Psi_S^{\text{BF}}(\mathbf{R}) \equiv \Psi_S[\mathbf{R}(\mathbf{X})] = \begin{vmatrix} \phi_1[\mathbf{x}_1(\mathbf{R})] & \phi_1[\mathbf{x}_2(\mathbf{R})] & \dots & \phi_1[\mathbf{x}_N(\mathbf{R})] \\ \phi_2[\mathbf{x}_1(\mathbf{R})] & \phi_2[\mathbf{x}_2(\mathbf{R})] & \dots & \phi_2[\mathbf{x}_N(\mathbf{R})] \\ \vdots & \vdots & \ddots & \vdots \\ \phi_N[\mathbf{x}_1(\mathbf{R})] & \phi_N[\mathbf{x}_2(\mathbf{R})] & \dots & \phi_N[\mathbf{x}_N(\mathbf{R})] \end{vmatrix}$$

# Interpreting backflow geometrically

A good way of looking at backflow transformations is as an addition which has a complementary effect to that of the Jastrow factor

- A Jastrow factor can change the “vertical” shape of a wave function, acting on it as a **positive envelope**
- A backflow transformation can **shift** the wave function in the “horizontal” direction

# Parametrisation of backflow

Want to construct  $\xi_i(\mathbf{R})$  as a sum of e-e, e-n and e-e-n functions:

$$\xi_i^{\text{e-e}} = \sum_{j \neq i}^{N_e} \eta_{ij} \mathbf{r}_{ij} \quad , \quad \eta_{ij} = \eta(r_{ij})$$

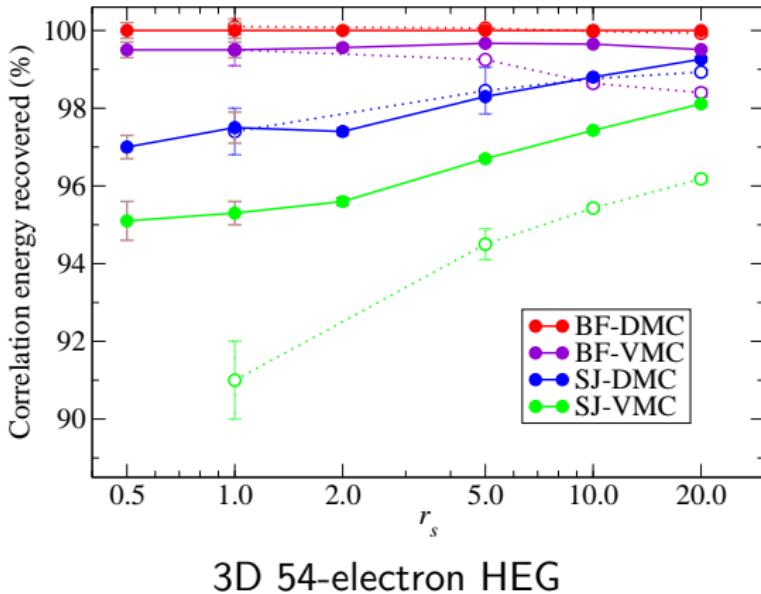

$$\xi_i^{\text{e-n}} = \sum_I^{N_n} \mu_{iI} \mathbf{r}_{iI} \quad , \quad \mu_{iI} = \mu(r_{iI})$$

$$\xi_i^{\text{e-e-n}} = \sum_{j \neq i}^{N_e} \sum_I^{N_n} (\Phi_i^{jl} \mathbf{r}_{ij} + \Theta_i^{jI} \mathbf{r}_{iI}) \quad , \quad \Phi_i^{jl} = \Phi_I(r_{ij}, r_{iI}, r_{JI})$$

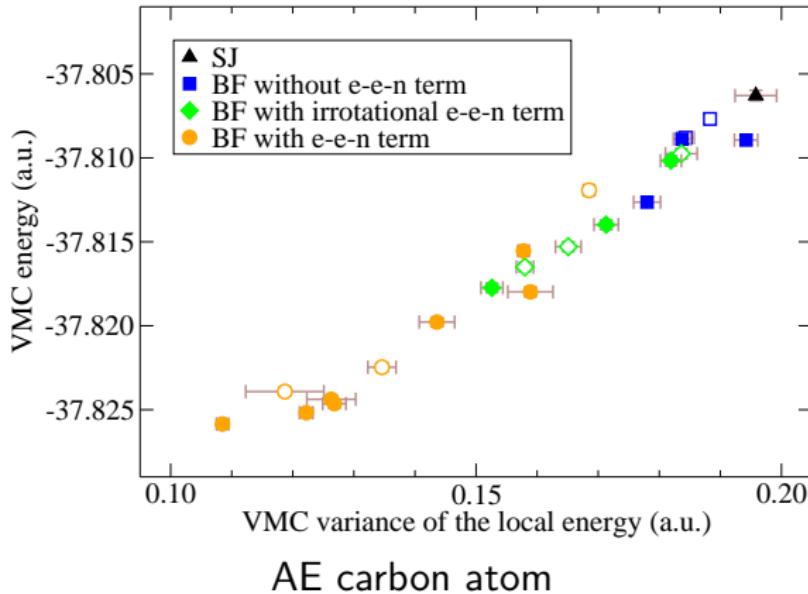

$$\Theta_i^{jI} = \Theta_I(r_{ij}, r_{iI}, r_{JI})$$

Total  $\xi_i$  is  $\xi_i^{\text{e-e}} + \xi_i^{\text{e-n}} + \xi_i^{\text{e-e-n}}$

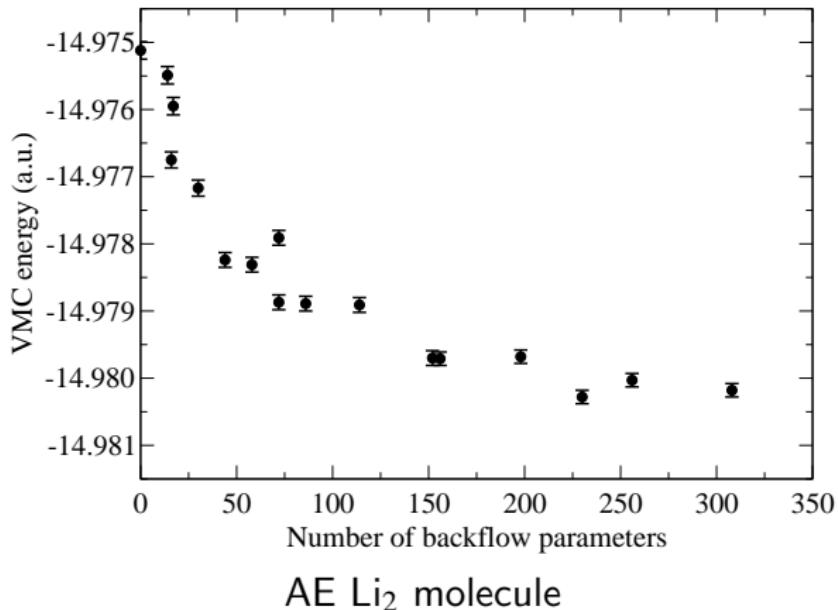

# Backflow results

# Backflow results

# Backflow results

## Backflow results

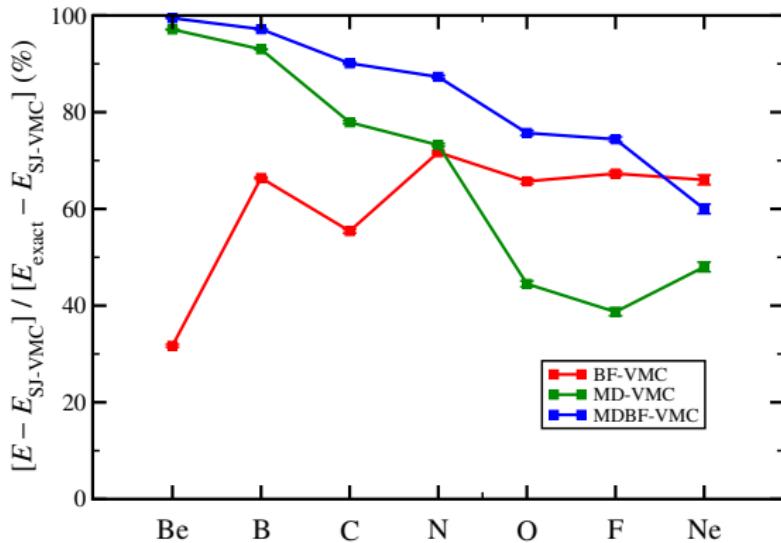

Properties of backflow:

- Variance of the local energy **reduced**
- Wave function update algorithms are more **costly**
- Non-local projection for PP energy requires lots of wave function evaluations → **costly**
- CBCA simpler, but EBEA still favourable

# What goes well with what?

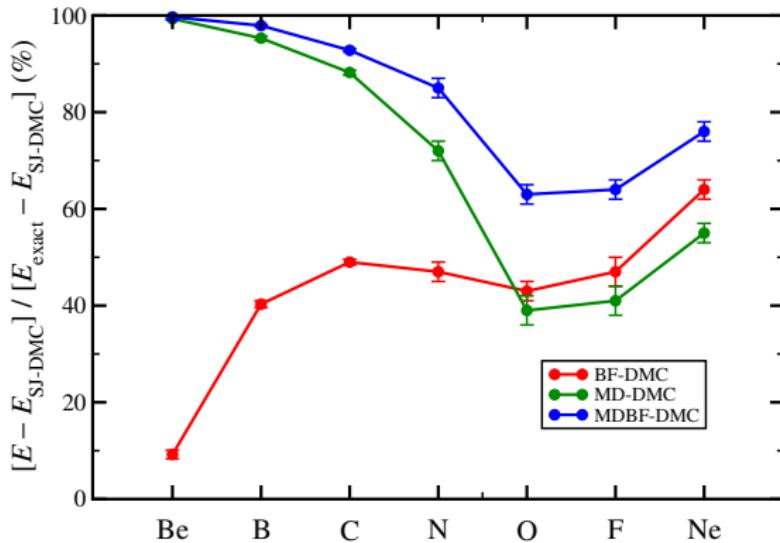

- **OO** and **BF**: orbital optimisation largely **overlaps** with backflow → only need to optimise orbitals on BF wave functions when initial orbitals fundamentally **wrong**
- **OO** and **MD**: probably the same case as OO and BF (data to compare OO, MD and OO+MD consistently?)
- **MD** and **BF**: excellent where MD is good, otherwise use BF only

# Multi-determinants vs. backflow

MD expansions can be very successful for small systems

# Multi-determinants vs. backflow

MD expansions can be very successful for small systems
